De 10⁴ Hz à 0.110 MHz : Comportement capacitif

$$Z_{C} = \frac{1}{c\omega} = \frac{1}{2\pi f}, f = 110kHz$$

$$Z_{C} = 10^{(3.683/20)} = 1.53\Omega$$

$$C = \frac{1}{2\pi fZ_{c}} = \frac{1}{2\pi * 10^{5} * 1.53} = 0.9\mu F$$

De 110Khz à 3 MHz comportement résistif

Pour f=3MHz:

$$Z_R = 10^{(2.84/20)} = 1.387\Omega$$

De 3 MHz à 15 MHz comportement inductif

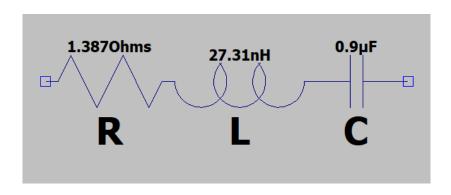

Pour f = 12MHz:

$$Z_{L} = L\omega = 2\pi fL, f = 12MHz$$

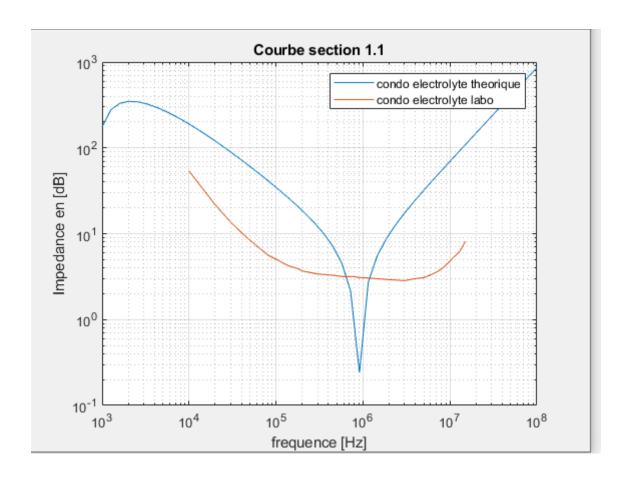

$$Z_{L} = 10^{(6.29/20)} = 2.06\Omega$$

$$L = \frac{2.06}{2\pi * 12 * 10^{6}} = 27.31nH$$

2. Impédance d'une inductance en fonction de la fréquence

L'inductance est modélisée par un condensateur en parallèle avec une résistance et une inductance qui sont en série :

$$(R + j\omega L) / / \frac{1}{j\omega C}$$

$$Z_{eq} = \frac{(R + j\omega L) * \frac{1}{j\omega C}}{(R + j\omega L) + \frac{1}{j\omega C}} = \frac{R + j\omega L}{1 - jC\omega^2 + jRC\omega}$$

2. Impédance d'une inductance en fonction de la fréquence – résultats expérimentaux

4. Les plages de fréquences

L'impédance agit comme :

Fréquence	Component
1kHz à 60kHz	une résistance
60kHz à 90kHz	une inductance
90kHz à 15MHz	un condensateur

5. L'effet de 50 ohms à l'entrée d'oscilloscope

En utilisant une entrée d'oscilloscope de 50 ohms, ce qui est >> Z_L, la system aura un comportement résistif. Donc la tension de sortie restera constante.
